ABSTRACT
The aim of this paper is that the study of laminar boundary layer flow on an Isothermal wall/adiabatic wall. The present study of this paper deals with two dimensional laminar boundary layer equation with steady state motion using similar transformation. The equation has been solved by Runge-Kutta method and Shooting technique. Results have been discussed by numerical solution and graphical representation.

Keywords: Renold’s Number, Prandtl’s Number, Pressure Gradient, Viscous Dissipation etc.

1. INTERODUCTION

Boundary layer may be defined by two type’s firstly laminar boundary layer secondly turbulent boundary layer. A laminar boundary layer is one where the flow takes place in each layers slide past the adjacent layers, these is in contrast to turbulent boundary layers are an intense agitation. In a laminar boundary layer any exchange of mass or momentum takes place only between adjacent layers on a microscope scale which is not visible to see from eyes. Laminar boundary layer are founded only when Renold’s numbers are small only other hand turbulent boundary laye are marked by mixing across several layers of it. The mixing is now on a microscopic scale there is an exchange of mass, momentum and energy on a much bigger scale composed by laminar boundary layer. Laminar boundary layer has large Renold’s number.

Laminar boundary layer come in various forms and can be loosely classified according to their structure and the circumstance under which they are created. The thin shear layer which develops on an oscillating body is an example of Stoke layer. While the Blasius boundary layer refers to the well known similarity solution of the study boundary layer attached with plain wall. The pervious related to this paper “N. Kafausstas & A. Karbis” “Numerical study of two dimensional laminar boundary layer
compressible flows with presser gradient and heat mass transfer” and other study “S. P. Mishra & G. C. Das” “Numerical solution of boundary layer MHD flow with viscous dissipation.”

2. MATHEMATICAL FORMULATION

We consider two dimensional laminar boundary equations. All the fluid properties are assumed to be constant throughout the motion. Under the usual boundary layer approximations the basic governing equations with viscous dissipation are.

\[
\frac{\partial u}{\partial x} + \frac{\partial u}{\partial y} = \text{(1)}
\]

Equation of Momentum \[\frac{\partial u}{\partial x} + \frac{\partial u}{\partial y} = \theta \frac{\partial^2 u}{\partial y^2} \text{ (2)}\]

Equation of Energy \[\frac{\partial T}{\partial x} + \frac{\partial T}{\partial y} = \alpha \frac{\partial^2 T}{\partial y^2} \text{ (3)}\]

Where \[\alpha = \frac{k}{\rho c_p}\]

It will be noted that the viscous dissipation term is omitted from the energy equation then the boundary conditions are

\[U = 0 \text{ at } y = 0 \quad V = 0 \text{ at } y = 0\]
\[\frac{\partial u}{\partial x} = 0 \text{ at } y = \infty\]
\[T = T_\infty \text{ at } y = \infty\]

The equation of continuity (1) is identically satisfied. Now it take the stream function \[\varphi\] then

\[u = \frac{\partial \varphi}{\partial y} \text{ and } v = -\frac{\partial \varphi}{\partial x}\]

The momentum and energy equation (2) and (3) Transformed into the corresponding following similar transform

\[\varphi(x, y) = k \sigma \eta f(\eta)\]
\[\frac{T - T_w}{T_\infty - T_w} = (\eta) \text{ (6)}\]

Where \[\eta = y \sqrt{\frac{k}{\lambda v}} \text{ and } k = \text{constant}\]

Momentum and Energy equations are transferred into following equations

\[ff'' + f''' = 0 \text{ (7)}\]
\[\theta'' + Pr \theta' = 0 \text{ (8)}\]

where \[\alpha = K/\mu C_p \text{ and } Pr = \mu C_p / \rho \text{ (Prandtl Number Solving equation (7) and (8) find the value of } \theta \text{ and } f. \text{ The corresponding boundary conditions are}\]

\[\eta = 0, f' = 0 \text{ and } f = 0, \eta = 0, f = 1 \text{ and } \eta = \infty, \theta' = 0 \text{ at } y = 0, \eta = 0\]
\[\theta = 0 \text{ at } y = \infty, \eta = \infty\]

3. RESULTS AND DISCUSSION

For results and discussion we solve the complete solution of equation (7) and (8) using Runge-Kutta Method and Shooting technique. The value of (f) depends on the value of \(\eta\) and also the value of temperature depends on
the value of $\eta$. The computations were done by a programme which uses a symbolic and computational computer language Matlab. Now we take the graphical solution.

\[
\eta = y \sqrt{\frac{f}{v}}
\]

4. **CONCLUSION**

The effect of temperature and the effect of velocity both are depend on the value of $\eta$. If the value of $\eta$ increase it’s also increase the temperature. Parameter $\alpha$ and the momentum boundary layer thickness decreases. Also, the dimensionless temperature profile as well as the thermal boundary layer thickness quickly reduces as increasing Pr. Similarly thermal boundary layer thickness decreases for some higher values of heat source parameter heat absorption occurs at the sheet. The rate of heat transfer increases with Prandtl number.
